## Cryptography and Data Security

Lecture 4:

4.1 Stream ciphers

4.2 Block cipher confidentiality modes of operation

Kaufman et al: Ch 4

Stallings: Ch 6, Ch 3

1

## Stream ciphers

- Stream ciphers are generally faster than block ciphers, especially when implemented in hardware.
- Stream ciphers have less hardware complexity.
- Stream ciphers can be adapted to process the plaintext bit by bit, or word by word, while block ciphers require buffering to accumulate the full plaintext block.
- Synchronous stream ciphers have no error propagation; encryption is done character by character with keys  $K_i$  that are independent of the data

$$C_i = E_{K_i}(P_i)$$

- Function E is simple, the function which computes the key sequence is complex
- Example: Vigenère cipher, One Time Pad

$$C_i = (P_i + K_i) \bmod 26$$

2

## Stream cipher encryption

### SENDER

(Secret key, Initial value)  $\rightarrow$  Key stream

(Key stream, Message)  $\rightarrow$  Ciphertext

### RECEIVER

(Secret key, Initial value)  $\rightarrow$  Key stream

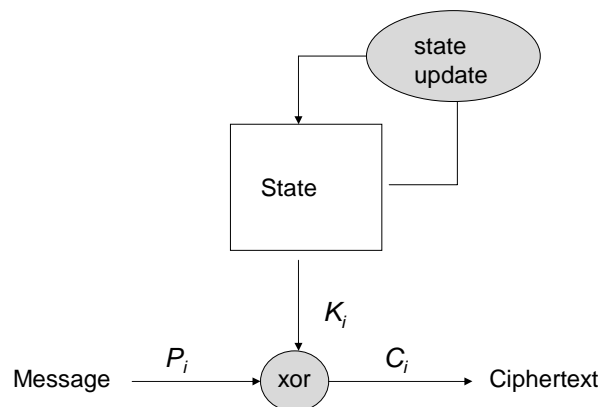

(Ciphertext, Key stream)  $\rightarrow$  Message

The initial value can be public or secret, but it must not repeat during the lifetime of the secret key.

This is the operation of the basic, so called *synchronous stream cipher*

3

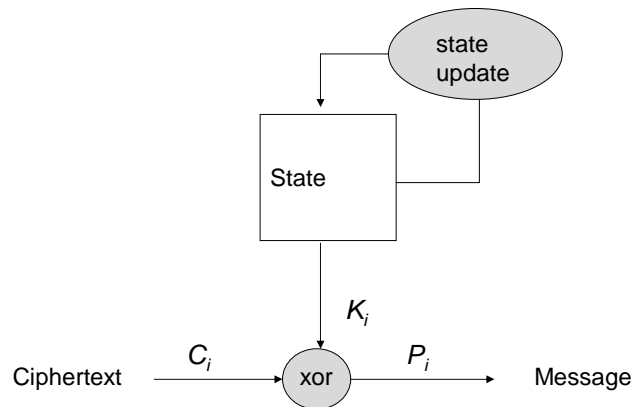

## Synchronous stream cipher: encryption

IV picks a different starting state for each new message

4

## Synchronous stream cipher: decryption

5

## Stream ciphers: Security

- Known plaintext gives known key stream. Chosen plaintext gives the same but nothing more.
- Chosen ciphertext attack may be a useful method for analysing a self-synchronising stream cipher.
- The attacker of a stream cipher may try to find one internal state of the stream cipher to obtain a functionally equivalent algorithm without knowing the key.
- Distinguishing a key stream sequence from a truly random sequence allows also the keystream to be predicted with some accuracy. Such attack is also called prediction attack.

Requirements:

- Long period
- The initial value can be public or secret, but it must not repeat during the lifetime of the secret key.
- A fixed initialisation value the stream cipher generates a different keystream for each key.

6

## Stream ciphers: Designs

Linear feedback shift register (LFSR). LFSRs are often used as the running engine for a stream cipher.

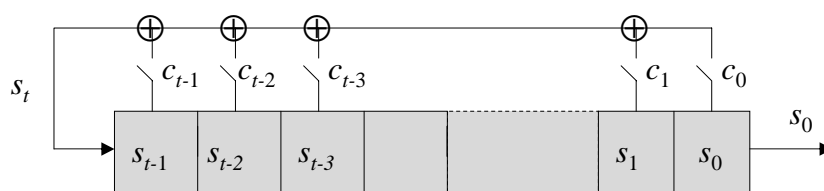

Stream cipher design based on LFSRs uses a number of different LFSRs and nonlinear Boolean functions coupled in different ways.

Three common LFSR-based types of stream cipher can be identified:

- *Nonlinear combination generators*: The keystream is generated as a nonlinear function of the outputs of multiple LFSRs
- *Nonlinear filter generators*: The keystream is generated as a nonlinear function of stages of a single LFSR.
- *Clock controlled generators*: In these constructions, the necessary nonlinearity is created by irregular clocking of the LFSRs. The GSM encryption algorithm A5/1 is an example of a stream cipher of this type.

7

## Linear Feedback Shift Register (LFSR)

$$s_t = \sum_{i=0}^{t-1} c_i s_i = c_{t-1} s_{t-1} + c_{t-2} s_{t-2} + \dots + c_0 s_0$$

The taps  $c_i$  are defined by giving the *feedback polynomial*

$$f(x) = x^t + c_{t-1}x^{t-1} + c_{t-2}x^{t-2} + \dots + c_1x + c_0$$

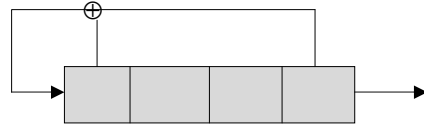

8

## LFSR: Example

NOTE: Everything is binary, that is, in bits.  
Sums are taken mod 2.

$$f(x) = x^4 + x^3 + 1$$

$\Rightarrow c_0 = c_3 = 1$  and  $c_1 = c_2 = 0$

Let us take this as an initial state:

0    0    1    1

Then the next state is this:

1    0    0    1

And so on:

0    1    0    0

0    0    1    0

0    0    0    1

1    0    0    0

For how long it goes?

...    ...    ...    ...

9

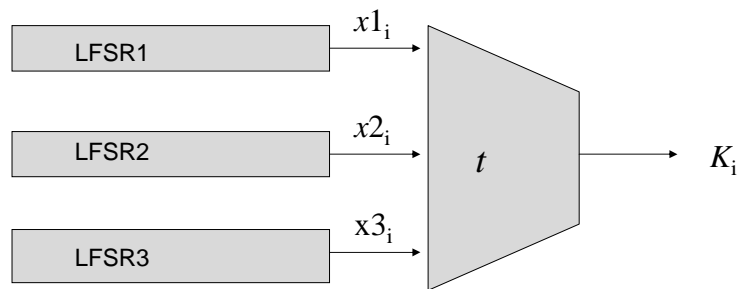

## LFSR statistical properties

- A full cycle of  $2^n - 1$  produces a sequence of length  $2^n - 1$  (maximum length).
- A maximum length sequence has ideal statistical properties:
- $2^{n-1} - 1$  zeroes and  $2^{n-1}$  ones
- One string of ones of length  $n$ ; one string of zeroes of length  $n-1$
- Also ones and zeroes occur in about equally many pairs, triples ... , and so on.
- is achieved using a so-called primitive polynomials.  
For a source of primitive polynomials see:  
<http://fchabaud.free.fr/English/default.php?COUNT=1&FILE0=Poly>

10

## Combination generator

Example: Threshold generator

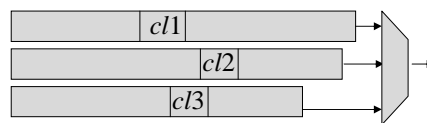

$t(x1, x2, x3) = 1$ , if at least two of the inputs are equal to 1  
0, otherwise

11

## Clock Controlled generators

A clocking sequence is derived. The clocking sequence determines how the LFSRs are shifted

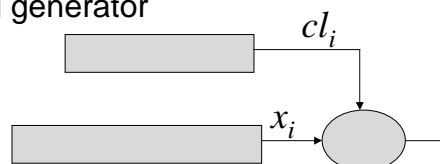

Example: A5/1

Clock bits are read. The LFSRs which are in majority, are shifted

Example: Shrinking generator

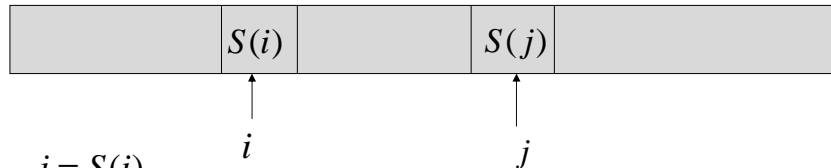

If the  $cl_i = 0$ ,  
then  $x_i$  is dropped

12

## RC4

Register of 256 octets initialised using the key.  
Counter  $i$  is set to zero. Then:

$$j = S(i)$$

$S(i)$  and  $S(j)$  are swapped

$$k = (j + S(j)) \bmod 256$$

$$\text{output} = S(k)$$

$$i = (i + 1) \bmod 256$$

13

## 4.2 Block cipher confidentiality modes of operation

Block ciphers (in general) not good as such

- AES modes of operations:
  - ELECTRONIC CODEBOOK MODE, ECB
  - CIPHER BLOCK CHAINING, CBC
  - CIPHER FEEDBACK, CFB
  - OUTPUT FEEDBACK, OFB
  - COUNTER MODE, CTR

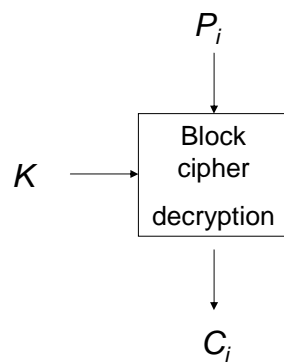

standardised by NIST, Special Publication 800-38A, see:  
<http://csrc.nist.gov/publications/nistpubs/index.html>

DES algorithm not good as such (small key size)

- Triple DES Special Publication 800-67

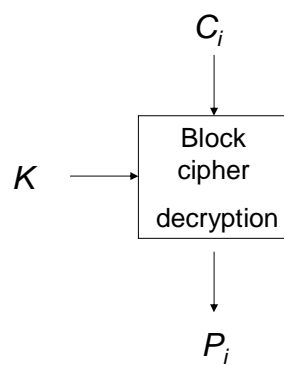

14

## Electronic Code Book Mode: Encryption

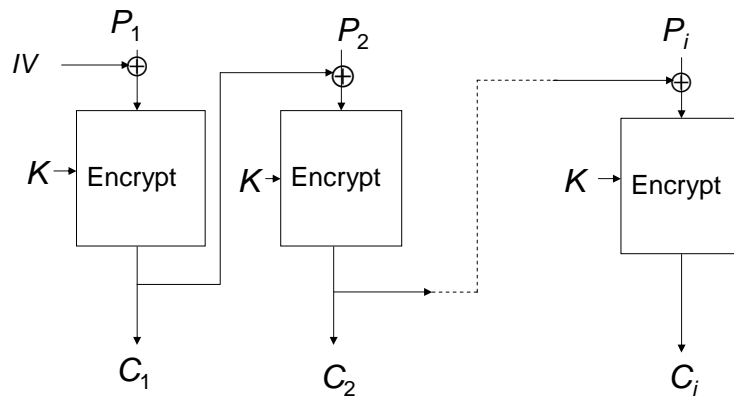

15

## Electronic Code Book Mode: Decryption

16

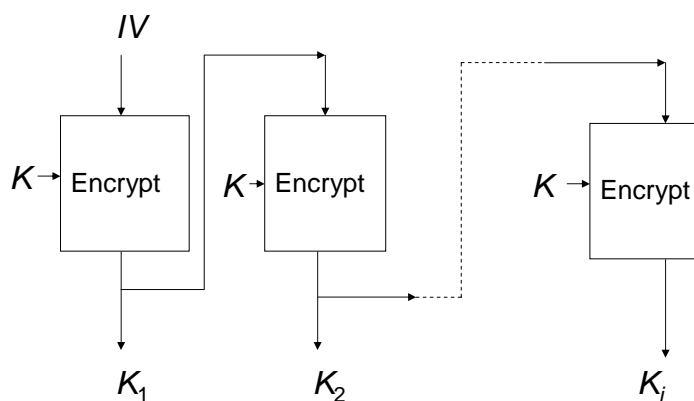

## Cipher Block Chaining Mode: Encryption

17

## Output Feed Back Mode

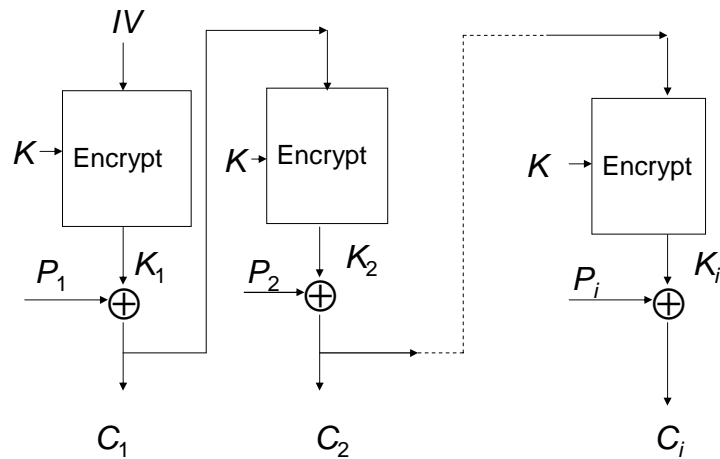

Synchronous Key Stream Generator:  
Identical for encryption and decryption

18

## Cipher Feed Back Mode: Encryption

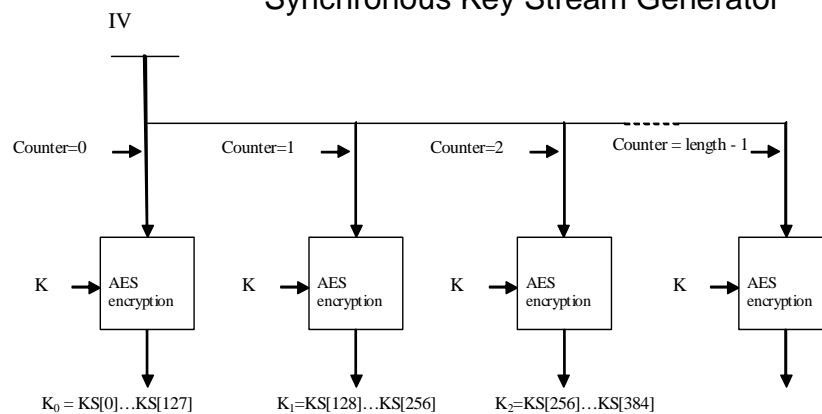

Self-Synchronising Stream Cipher: Decryption device is identical, only  $P_i$  and  $C_i$  change places

19

## Counter Mode

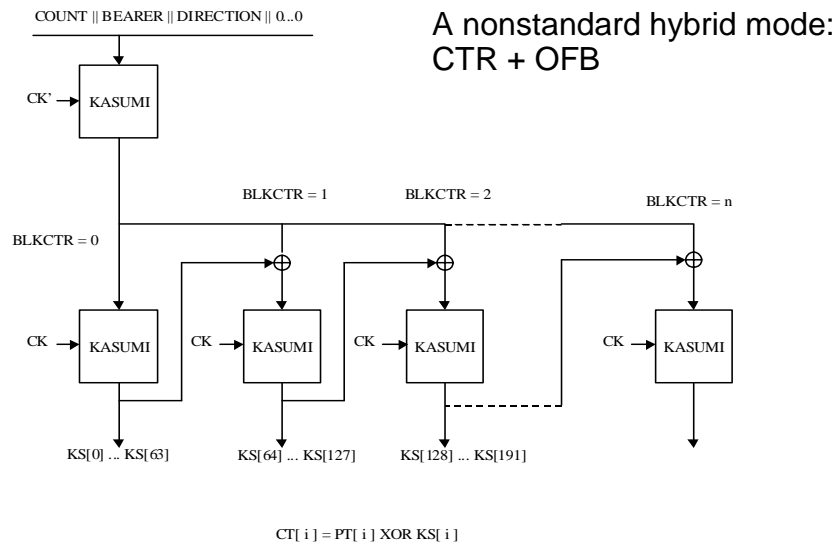

Synchronous Key Stream Generator

20

## UMTS Encryption algorithm f8

## Triple DES (TDEA)

DES algorithm not good as such (small key size)

Double DES with two different keys  $K_1$  and  $K_2$  not good either (security not more than single DES) due to the Meet-in-the-Middle Attack (see next slide):

Triple DES Special Publication 800-67, see

<http://csrc.nist.gov/publications/nistpubs/index.html>

Triple DES with two keys

$$C = E_{K_1}(D_{K_2}(E_{K_1}(P)))$$

reduces to single DES, in case  $K_1 = K_2$ .

## Meet in the Middle

Double DES with two different keys  $K_1$  and  $K_2$  not good either (security is not more than single DES due to the Meet-in-the-Middle Attack. Such attack can be launched when the attacker has two known plaintext-ciphertext pairs  $(P, C)$  and  $(P', C')$ . For such pairs obtained using the secret keys  $K_1$  and  $K_2$  the attacker has  $C = E_{K_2}(E_{K_1}(P))$  and  $C' = E_{K_2}(E_{K_1}(P'))$  or what is the same:  $D_{K_2}(C) = E_{K_1}(P)$  and  $D_{K_2}(C') = E_{K_1}(P')$ .

Now we make a table T with a complete listing of all possible pairs  $K_2, D_{K_2}(C)$  as  $K_2$  runs through all possible  $2^{56}$  values. The table has  $2^{56}$  rows with 120 bits on each row. We make one more column to this table, and fill it with  $K_1$  values as follows: For each  $K_1$  we compute the value  $E_{K_1}(P)$  and search in the table T for a match  $D_{K_2}(C) = E_{K_1}(P)$ . For each  $K_2$  we expect to find a (almost) unique  $K_1$  such that such a match occurs. Now we go through all key pairs  $K_1, K_2$  suggested by table T, and test against the equation  $D_{K_2}(C') = E_{K_1}(P')$  we have based on the second plaintext – ciphertext pair  $(P', C')$ . The solution is expected to be unique. The size of table T is  $2^{56} (56 + 64 + \sim 56 \text{ bits}) < 2^{64}$  bits, which is the memory requirement of this attack. The number of encryptions (decryptions) needed is about  $4 \cdot 2^{56} = 2^{58}$ .
