1.

A rational engineer wants to travel from Otaniemi to Kirkkonummi using public transportations. There are three possible routes:

- First take a bus to downtown Helsinki (ticket 15 mk) and then from there to Kirkkonummi by train (24 mk).
- Take a bus to Leppävaara (10 mk) and from there to Kirkkonummi by train (16 mk)
- Take a bus to Tapiola, change to another bus and go to Kauklahti (10 mk) and board a train from there (10 mk).

The durations of the travel routes are shown in the above figure.

- Let the engineer have a cost function $U(t, m) = m + at$, where m is the cost, t is the duration of trip, and a his hourly rate. What route should the engineer take so that $U(t, m)$ is minimized, when $a = 40\text{mk/h}$. What should the hourly rate be so that route III would be better than the route II? Is one of the routes clearly better or worse than the others?
- Let cost function $U(t_1, t_2, m) = a_1 t_1 + a_2 t_2 + m$, where t_1 is the time spent in a bus, t_2 the time spent in a train, $a_1 = 1.5a$ and $a_2 = 0.5a$. What is now the best route?
- Let $U(t)$ be as in a-part, but the busses may be late according to the following probability distribution:

Line	0 min	1 min	5 min	10 min	15 min
O-Hki	75%	20%	5%	-	-
O-T	80%	15%	5%	-	-
T-KL	20%	20%	20%	20%	20%
O-LV	30%	20%	-	20%	30%

What choice is now the best?
