INTELLIGENT AGENTS

Outline

- Agents and Environments
- Good Behavior and Rationality
- Nature of Environments
- Structure of Agents

Based on the textbook by Stuart Russell & Peter Norvig:

Artificial Intelligence: Modern Approach, (2nd Edition)

Chapter 2

1. AGENTS AND ENVIRONMENTS

Definition. Russell and Norvig define agents as follows:

"An agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators."

Examples.

A physical robot

- Sensors: video camera, laser scanner, microphone, ...
- Actuators: motor, switch, display, speaker, ...

A software robot (softbot)

- Percepts: encoded bit strings
- Sensors and actuators: calls to operating system, libraries or other programs
- Calls to sensor programs provide input for the agent,

Mapping Percept Sequences to Actions

- Agent's behavior depends only on its percept sequence to date.
- An agent can be designed by specifying which action an agent ought to take in response to any given percept sequence.
- Such a mapping (agent function) can be represented as a table or as an agent program.

Example. Consider a calculator agent that computes square-roots of positive integers (accurate to 15 decimals).

Approach 1: store square roots in a very large table.
Approach 2: implement the ideal mapping as a program.

The latter approach is clearly more compact and flexible.
**Example.** A vacuum cleaner world with just two locations.

<table>
<thead>
<tr>
<th>Percept sequence</th>
<th>Action</th>
</tr>
</thead>
<tbody>
<tr>
<td>[A, Clean]</td>

# 2. GOOD BEHAVIOR AND RATIONALITY

- A **rational agent** should do the right thing, but how and when do we evaluate agent’s success?
- A **performance measure** determines how successful an agent is (by an outside observer).

**Problems:**
- Self-deception: humans typically say they did not really want something after they are unsuccessful at getting it.
- Malpractice if performance is measured only instantly.
- You get what you ask for!
  (Performance measures have to be carefully chosen.)

© 2005 HUT / Laboratory for Theoretical Computer Science

---

**Rational Agents**

Rationality depends on four things:

- The performance measure which defines the criterion of success,
- The agent’s prior knowledge of the environment,
- The actions that the agent can perform,
- The agent’s percept sequence to date (complete perceptual history).

**Definition.** *(Rational agent)*

For each possible percept sequence, a rational agent should select an action that is **expected to maximize its performance measure**, given the evidence provided by the percept sequence and whatever built in knowledge the agent has.

© 2005 HUT / Laboratory for Theoretical Computer Science

---

**Omniscience vs. Rationality**

An omniscient agent

- knows the **actual** outcomes of its actions and acts accordingly; and
- is impossible in reality.

**Example.** A person is crossing a street, as (s)he noticed a friend across the street and there is no traffic nearby.

Is this person acting rationally if (s)he is crashed by a cargo door falling off a passing airplane?

**Rationality:** expected success given what has been perceived,

© 2005 HUT / Laboratory for Theoretical Computer Science
Information Gathering

Example. Often begin rational requires performing actions in order to acquire information about the environment.

- For instance, crossing a street without looking is too risky.

Example. A clock can be thought as a simple (even degenerate) agent that keeps moving its hands (or displaying digits) in the proper way.
- This can be thought as rational action given what kind of functionality one expects from a clock in general.
- However, many clocks are unable to take changing time zones into account automatically. This is quite acceptable if the clock does not have a mechanism for perceiving time zones.

3. NATURE OF ENVIRONMENTS

- A task environment specifies a “problem” to which a rational agent is a “solution”.
- Task environments can be roughly specify by giving a PEAS (Performance, Environment, Actuators, Sensors) description.

Example. Task environment for an automated taxi.

<table>
<thead>
<tr>
<th>Task driver</th>
<th>Performance Measure</th>
<th>Environment</th>
<th>Actuators</th>
<th>Sensors</th>
</tr>
</thead>
<tbody>
<tr>
<td>Safe, fast, leg, comfortable trip, maximize profit</td>
<td>Healthy patient, minimizes costs, has health</td>
<td>Patient, hospital staff</td>
<td>Display qualitative, tacit, diagnostic, treatments</td>
<td>Keyboard entry of symptoms, findings, patient's awareness</td>
</tr>
<tr>
<td>Satellite image analysis system</td>
<td>Correct image classification</td>
<td>Raw data from sitting at desk</td>
<td>Display categorization of inputs</td>
<td>Color blind speech</td>
</tr>
<tr>
<td>Parking robot</td>
<td>Percentage of cars in correct lane</td>
<td>Car driver looks at camera, brake</td>
<td>J.I.E.S. and head</td>
<td>Camera, light, angle sensors</td>
</tr>
<tr>
<td>Ordinary controller</td>
<td>Maximizes purity, yield, safety</td>
<td>Refinery operators</td>
<td>Valve, pump, heater, display</td>
<td>Temperature, pressure, chemical sensors</td>
</tr>
<tr>
<td>Interactive English tutor</td>
<td>Maximizes student's score on test</td>
<td>Set of students, testing agency</td>
<td>Display exercises, suggestions, correction</td>
<td>Keyboard entry</td>
</tr>
</tbody>
</table>

Autonomy

- An agent lacks autonomy if its actions depend solely on its built-in knowledge about the environment.
- A system is autonomous to the extent that its behavior is determined by its own experience.
- Flexible operation in a variety of environments demands ability to learn (in addition to initial knowledge).

Example. After digging its nest and laying its eggs, a dung beetle fetches a ball of dung to plug the entrance.
- Even if the ball is removed from its grasp en route, the beetle continues and mimics the procedure to the very end.
Properties of Task Environments

Environments can be categorized by several aspects such as

- Fully vs. partially observable state of the environment
  Also: effectively fully observable
- Deterministic vs. stochastic outcomes of agent’s actions
- Episodic vs. sequential
- Static vs. dynamic
  Also: semidynamic (performance degrades over time)
- Discrete vs. continuous
- Single agent vs. multiagent (competitive or cooperative)

Examples. Analyzing properties of a number of familiar environments.

<table>
<thead>
<tr>
<th>Environment</th>
<th>Accessible</th>
<th>Deterministic</th>
<th>Episodic</th>
<th>Static</th>
<th>Discrete</th>
</tr>
</thead>
<tbody>
<tr>
<td>Chess with a clock</td>
<td>Yes</td>
<td>Yes</td>

<tr>
<td>Interactive English tutor</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>No</td>
<td>Yes</td>
</tr>
</tbody>
</table>

- Some of the properties are dependent on how the environments and agents are conceptualized.

4. STRUCTURE OF AGENTS

- The goal is to design an agent program which implements the mapping from percepts to actions.
- An architecture is a computing device that makes percepts available, runs the program and feeds action choices to actuators.
- Summarizing: agent = architecture + program.

Agent Programs

A skeleton for agent programs:

- A single percept is obtained as input.
- Memory is used for storing the percept history (if necessary).
- The program chooses and outputs an action to be executed next.

```lisp
(defun SKELETON-AGENT (percept) (return action
  static memory, the agent's memory of the world
  memory = UPDATE-MEMORY (memory, percept)
  action = CHOOSE-BEST-ACTION (memory)
  memory = UPDATE-MEMORY (memory, action)
  return action
)
```

- The performance measure is not a part of the program.
Using Lookup Tables

- An agent program that looks up the action from a table:

  ```python
  def lookup_agent_percept(precepts, table):
      return table[precepts]
  ```

- Drawbacks of lookup table agents:
  1. The lookup table becomes easily very large
     (a chess playing agent would need a table with 35^{100} entries).
  2. The table is difficult to build and maintain.
  3. The resulting agent does not have autonomy at all.
  4. It would take forever to learn the right values for all entries.

Simple Reflex Agents

- Condition-action rules provide a way to represent common regularities appearing in input/output associations:
  ```
  if car in front is braking then initialize braking
  ```

- It is even possible to learn such rules on the fly.

- Humans also have many such connections some of which are learned responses and some of which are innate reflexes
  (such as eye blinking in order to protect the eye).

- Mimicking reflexes of living creatures, a reflex agent chooses the next action on the basis of the current percept.

- No track of the world/environment is kept.

Different Kinds of Agent Programs

In the sequel, we will consider four kinds of agent programs:

- Simple reflex agents
- Model-based reflex agents
- Goal-based agents
- Utility-based agents

Then we discuss a general way to incorporate learning into these.
**Model-based Reflex Agents**

- The choice of actions may depend on the entire percept history.
- Sensors do not necessarily provide access to the complete state of the environment.
- The agent keeps track of the world by extracting relevant information from percepts and storing it in its memory.
- Using a model of the environment, the agent may try to estimate 1, how the environment evolves in the (near) future, and 2, how the environment is affected by the agent's actions.

**Example.** In our taxi driving example, actions may depend on the state, e.g., the position of an overtaking car.

**Goal-based agents**

- Knowing about the current state of the environment is not necessarily enough for deciding what to do.
- In addition, the agent may need goals to distinguish which situations are desirable and which are not.
- Goal information can be combined with the agent's knowledge about the results of possible actions in order to choose an action leading to a goal.
- Problem: goals are not necessarily achievable by a single action.
- Search and planning are subfields of AI devoted to finding actions sequences that achieve the agent's goals.

**A schematic diagram and a skeletal agent program for a model based reflex agent:**

![Diagram](image1)

**Agent**

- Goals
  - How the world evolves
  - What my actions do
- Environment
  - What the world is like now
  - What my actions should do now
- Actuators

**Function: REFLX-AGENT(WHOLE-STATE, percept)[returns active]
  - state - state, a description of the current world state
  - rules - a set of condition-action rules
  - goal - goal (agent's goal)
  - action - REFLX-ACTION(则)
  - return active

**A schematic diagram for a goal-based agent:**

![Diagram](image2)

**Agent**

- Goals
  - What action I should do now
- Environment
  - What the world is like now
  - What it will be like if I do action A
- Actuators

**Additional flexibility compared to previous designs:** the behavior of a goal-based agent can be changed by changing its goal(s).
Utility-based agents

- Goals alone are not sufficient for decision making if there are several ways of achieving them.
- Further problem: agents may have several conflicting goals that cannot be achieved simultaneously.
- If an agent prefers one world state to another state then the former state has higher utility for the agent.
- Utility is a function that maps a state onto a real number.
- A utility function can be used for (i) choosing the best plan, (ii) resolving conflicts among goals, and (iii) estimating the usefulness of an agent if the outcomes of actions are uncertain.

Learning Agents

- A learning element is responsible for improving the performance element, which corresponds to an entire agent.
- The learning element gets feedback from a critic on the performance of the agent.
- A problem generator suggests actions that will lead to new and informative experiences.
- Sometimes the percepts of the agent include rewards or penalties (such as pain and hunger) that can be utilized in learning.

A schematic diagram for a utility-based agent:

- An agent that possesses an explicit utility function can make rational decisions, but may have to compare the utilities achieved by different courses of actions.
Programs Simulating Environments

procedure RUN-ENVIRONMENT(state, UPDATE-FN, agents, termination)
  inputs: state, the initial state of the environment
  UPDATE-FN, function to modify the environment agents, a set of agents
  termination, a predicate to test when we are done
  repeat
    for each agent in agents do
      PERCEPTR(agent) ← GET-PERCEPTION(agent, state)
    end
    for each agent in agents do
      ACTION(agent) ← PROGRAM(agent)(PERCEPTION(agent))
    end
    state ← UPDATE-FN(state, agents, state)
  until termination(state)

Agents are typically designed to work correctly in a class of environments (that is to be covered by a simulator somehow).
Agent programs should not have other access than perceptions to the state of the program simulating their environment!

© 2005 HUT / Laboratory for Theoretical Computer Science

The performance of agents can be measured by inserting special measurement code to simulator programs.

function RUN-EVAL-ENVIRONMENT(state, UPDATE-FN, agents, termination, PERFORMANCE-FN) returns scores
  local variables: scores, a vector the same size as agents, all 0
  repeat
    for each agent in agents do
      PERCEPT(agent) ← GET-PERCEPTION(agent, state)
    end
    for each agent in agents do
      ACTION(agent) ← PROGRAM(agent)(PERCEPT(agent))
    end
    state ← UPDATE-FN(state, agents, state)
    scores ← PERFORMANCE-FN(scores, agents, state)
  until termination(state)
  return scores /* change */

SUMMARY

- An agent program maps a percept (sequence) to an action.
- Agent = architecture + agent program.
- A rational agent tries to maximize its performance measure.
- Task environments can be described by PEAS descriptions.
- Various agent types: reflex agents with(out) internal state, goal-based agents, utility-based agents.
- Important aspects of agent program design: efficiency, compactness, flexibility.

QUESTIONS

- Analyze soccer playing agents by writing down
  1. a PEAS description and
  2. the main properties of the environment.
- Consider the following designs for soccer playing agents:
  1. Simple reflex agent
  2. Model-based reflex agent
  3. Agent with explicit goals
  4. Utility-based agent
  5. Learning agent
What kind of functionality can be implemented in terms of these?
