INTELLIGENT AGENTS

Intelligent Agents

Outline

- ➤ Agents and Environments
- ➤ Good Behavior and Rationality
- ➤ Nature of Environments
- ➤ Structure of Agents

Based on the textbook by Stuart Russell & Peter Norvig:

Artificial Intelligene, Modern Approach. (2nd Edition)

Chapter 2

○ 2005 HUT / Laboratory for Theoretical Computer Science

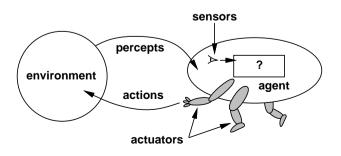

T-79.230 / Spring 2005

Intelligent Agents

1. AGENTS AND ENVIRONMENTS

Definition. Russell and Norvig define agents as follows:

"An agent is anything that can be viewed as perceiving its environment through sensors and acting upon that environment through actuators."

Examples.

A physical robot

- ➤ Sensors: video camera, laser scanner, microphone, ...
- ➤ Actuators: motor, switch, display, speaker, ...

A software robot (softbot)

- ➤ Percepts: encoded bit strings
- > Sensors and actuators: calls to operating system, libraries or other programs
- ➤ Calls to sensor programs provide input for the agent.

Intelligent Agents

Mapping Percept Sequences to Actions

- ➤ Agent's behavior depends only on its percept sequence to date.
- ➤ An agent can be designeby

"specifying which action an agent ought to take in response to any given percept sequence".

> Such a mapping (agent function) can be represented as a table or as an agent program.

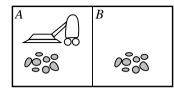

Example. Consider a calculator agent that computes square-roots of positive integers (accurate to 15 decimals).

Approach 1: store square roots in a very large table.

Approach 2: implement the ideal mapping as a program.

The latter approach is clearly more compact and flexible.

Example. A vacuum-cleaner world with just two locations.

Percept sequence	Action
[A,Clean]	Right
[A, Dirty]	Suck
[B,Clean]	Left
[B,Dirty]	Suck
[A,Clean],[A,Clean]	Right
[A,Clean],[A,Dirty]	Suck

Intelligent Agents

2. GOOD BEHAVIOR AND RATIONALITY

- ➤ A rational agent should do the right thing, but how and when do we evaluate agent's success?
- ➤ A performance measure determines how successful an agent is (by an outside observer).

Problems:

- ➤ Self-deception: humans typically say they did not really want something after they are unsuccessful at getting it.
- ➤ Malpractice if performance is measured only instantly.
- ➤ You get what you ask for! (Performance measures have to be carefully chosen.)

Rational Agents

Rationality depends on four things:

- ➤ The performance measure which defines the criterion of success.
- ➤ The agent's prior knowledge of the environment.
- ➤ The actions that the agent can perform.
- ➤ The agent's percept sequence to date (complete perceptual history).

Definition (Rational agent)

For each possible percept sequence, a rational agent should select an action that is expected to maximize its performance measure, given the evidence provideby the percept sequence and whatever built-in knowledge the agent has.

Intelligent Agents

Omniscience vs. Rationality

An omniscient agent

- ➤ knows the actual outcomes of its actions and acts accordingly; and
- ➤ is impossible in reality.

Example. A person is crossing a street, as (s)he noticed a friend across the street and there is no traffic nearby.

Is this person acting rationally if (s)he is crashedy a cargo door falling off a passing airplane?

Rationality: expected success given what has been perceived.

Information Gathering

Example. Often begin rational requires performing actions in order to acquire information about the environment.

➤ For instance, crossing a street without looking is too risky.

Example. A clock can be thought as a simple (even degenerate) agent that keeps moving its hands (or displaying digits) in the proper way.

- This can be thought as rational action given what kind of functionality one expects from a clock in general.
- However, many clocks are unable to take changing time zones into account automatically. This is quite acceptable if the clock does not have a mechanism for perceiving time zones.

T-79.230 / Spring 2005

Intelligent Agents

Autonomy

- ➤ An agent lacks autonomy if its actions depend solely on its built-in knowledge about the environment.
- ➤ A system is *autonomous* to the extent that its behavior is determined by its own experience.
- Flexible operation in a variety of environments demands ability to learn (in addition to initial knowledge).

Example. After digging its nest and laying its eggs, a dung beetle fetches a ball of dung to plug the entrance.

➤ Even if the ball is removed from its grasp en route, the beetle continues and mimics the procedure to the very end.

10

3. NATURE OF ENVIRONMENTS

- ➤ A task environment specifies a "problem" to which a rational agent is a "solution".
- ➤ Task environments can be roughly specifiedly giving a PEAS (Performance, Environment, Actuators, Sensors) description.

Example. Task environment for an automated taxi.

Agent Type	Performance Measure	Environment	Actuators	Sensors
Taxi driver	Safe, fast, legal, comfortable trip, maximize profits	Roads, other traffic, pedestrians customers	Steering, accelerator brake, signal, horn, display	Cameras, sonar speedometer GPS, odometer accelerometer, engine sensors, keyboard

© 2005 HUT / Laboratory for Theoretical Computer Science

T-79.230 / Spring 2005

Intelligent Agents

12

Examples. PEAS Descriptions of some task environments.

Agent Type	Performance Measure	Environment	Actuators	Sensors	
Medical diagnosis system	Healthy patient minimize costs, lawsuits	Patient, hospital staff	Display questions, tests, diagnoses, treatments	Keyboard entry of symptoms, findings, patient's answers	
Satellite image analysis system	Correct image categorization	Downlink from orbiting satellite	Display categorization of scene	Color pixel arrays	
Part-picking robot	Percentage of parts in correct bins	Conveyor belt with parts, bins	Jointed arm and hand	Camera, joint angle sensors	
Refinery controller	Maximize purity, yield, safety	Refinery, operators	Valves, pumps heaters, displays	Temperature, pressure, chemical sensors	
Interactive English tutor	Maximize student's score on test	Set of students, testing agency	Display exercises, suggestions, corrections	Keyboard entry	

Properties of Task Environments

Intelligent Agents

Environments can be categorizeby several aspects such as

- Fully vs. partially observable state of the environment Also: effectively fully observable
- ➤ Deterministic vs. stochastic outcomes of agent's actions
- ➤ Episodic vs. sequential
- > Static vs. dynamic

Also: semidynamic (performance degrades over time)

- ➤ Discrete vs. continuous
- ➤ Single agent vs. multiagent (competitive or cooperative)

© 2005 HUT / Laboratory for Theoretical Computer Science

T-79.230 / Spring 2005

Intelligent Agents

Examples. Analyzing properties of a number of familiar environments.

Environment	Accessible	Deterministic	Episodic	Static	Discrete
Chess with a clock	Yes	Yes	No	Semi	Yes
Chess without a clock	Yes	Yes	No	Yes	Yes
Poker	No	No	No	Yes	Yes
Backgammon	Yes	No	No	Yes	Yes
Taxi driving	No	No	No	No	No
Medical diagnosis system	No	No	No	No	No
Image-analysis system	Yes	Yes	Yes	Semi	No
Part-picking robot	No	No	Yes	No	No
Refinery controller	No	No	No	No	No
Interactive English tutor	No	No	No	No	Yes

➤ Some of the properties are dependent on how the environments and agents are conceptualized.

- ➤ The goal is to design an agent program which implements the mapping from percepts to actions.
- ➤ An architecture is a computing device that makes percepts available, runs the program and feeds action choices to actuators.
- ➤ Summarizing: agent = architecture + program.

16

Agent Programs

A skeleton for agent programs:

- ➤ A single percept is obtained as input.
- ➤ Memory is used for storing the percept history (if necessary).
- ➤ The program chooses and outputs an action to be executed next.

function Skeleton-Agent(percept) returns action static: memory, the agent's memory of the world

memory

UPDATE-MEMORY(memory, percept) $action \leftarrow CHOOSE-BEST-ACTION(memory)$ memory ← UPDATE-MEMORY(memory, action)

➤ The performance measure is not a part of the program.

Using Lookup Tables

➤ An agent program that looks up the action from a table:

function TABLE-DRIVEN-AGENT(percept) returns action static: percepts, a sequence, initially empty

table, a table, indexed by percept sequences, initially fully specified

append percept to the end of percepts $action \leftarrow LOOKUP(percepts, table)$

return action

- ➤ Drawbacks of lookup table agents:
 - 1. The lookup table becomes easily very large (a chess playing agent would need a table with 35^{100} entries).
 - 2. The table is difficult to build and maintain.
 - 3. The resulting agent does not have autonomy at all.
 - 4. It would take forever to learn the right values for all entries.

Different Kinds of Agent Programs

In the sequel, we will consider four kinds of agent programs:

- ➤ Simple reflex agents
- ➤ Model-based reflex agents
- ➤ Goal-based agents
- ➤ Utility-based agents

Then we discuss a general way to incorporate learning into these.

➤ Condition-action rules provide a way to represent common regularities appearing in input/output associations:

if car-in-front-is-braking then initialize-braking

- ➤ It is even possible to learn such rules on the fly.
- ➤ Humans also have many such connections some of which are *learned responses* and some of which are *innate reflexes* (such as eye blinking in order to protect the eye).
- ➤ Mimicking reflexes of living creatures, a **reflex agent** chooses the next action on the basis of the current percept.
- ➤ No track of the world/environment is kept.

T-79.230 / Spring 2005

Intelligent Agents

20

➤ The structure of a simple reflex agent as a schematic diagram and the corresponding skeletal agent program:

function Simple-Reflex-AGENT(percept) returns action static: rules, a set of condition-action rules state ← INTERPRET-INPUT(percept)

rule ← RULE-MATCH(state, rules) action ← RULE-ACTION[rule]

➤ Rules provide an efficient representation, but one problem is that decision making is seldom possible on the basis of a single percept.

Model-based Reflex Agents

Intelligent Agents

- ➤ The choice of actions may depend on the entire percept history.
- ➤ Sensors do not necessarily provide access to the complete state of the environment.
- ➤ The agent keeps track of the worlby extracting relevant information from percepts and storing it in its memory.
- ➤ Using a **model** of the environment, the agent may try to estimate
 - 1. how the environment evolves in the (near) future, and
 - 2. how the environment is affected by the agent's actions.

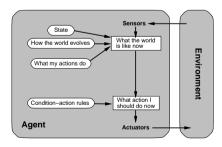

Example. In our taxi driving example, actions may depend on the state, e.g. the position of an overtaking car.

© 2005 HUT / Laboratory for Theoretical Computer Science

T-79.230 / Spring 2005

Intelligent Agents

➤ A schematic diagram and a skeletal agent program for a model-based reflex agent:

function REFLEX-AGENT-WITH-STATE(percept) returns action static: state, a description of the current world state rules, a set of condition-action rules

 $state \leftarrow \text{UPDATE-STATE}(state, percept) \\ rule \leftarrow \text{RULE-MATCH}(state, rules) \\ action \leftarrow \text{RULE-ACTION}[rule] \\ state \leftarrow \text{UPDATE-STATE}(state, action) \\$

return action

Goal-based agents

- ➤ Knowing about the current state of the environment is not necessarily enough for deciding what to do.
- ➤ In addition, the agent may need **goals** to distinguish which situations are desirable and which are not.
- ➤ Goal information can be combined with the agent's knowledge about the results of possible actions in order to choose an action leading to a goal.
- ➤ Problem: goals are not necessarily achievable by a single action.
- ➤ **Search** and **planning** are subfields of AI devoted to finding actions sequences that achieve the agent's goals.

22

T-79.230 / Spring 2005

Intelligent Agents

24

➤ A schematic diagram for a goal-based agent:

➤ Additional flexibility compared to previous designs: the behavior of a goal-based agent can be changeby changing its goal(s).

26

Utility-based agents

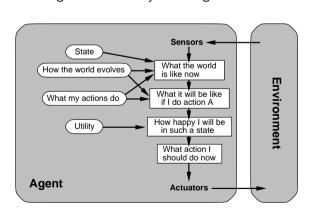

- ➤ Goals alone are not sufficient for decision making if there are several ways of achieving them.
- ➤ Further problem: agents may have several conflicting goals that cannot be achieved simultaneously.
- ➤ If an agent prefers one world state to another state then the former state has higher utility for the agent.
- ➤ Utility is a function that maps a state onto a real number.
- ➤ A utility function can be used for (i) choosing the best plan, (ii) resolving conflicts among goals, and (iii) estimating the successfulness of an agent if the outcomes of actions are uncertain.

T-79.230 / Spring 2005

Intelligent Agents

➤ A schematic diagram for a utility-based agent:

➤ An agent that possesses an *explicit* utility function can make rational decisions, but may have to compare the utilities achieved by different courses of actions.

- ➤ A learning element is responsible for improving the performance element, which corresponds to an entire agent.
- ➤ The learning element gets feedback from a **critic** on the performance of the agent.
- ➤ A **problem generator** suggests actions that will lead to new and informative experiences.
- ➤ Sometimes the percepts of the agent include *rewards* or *penalties* (such as pain and hunger) that can be utilized in learning.

30

Programs Simulating Environments

Intelligent Agents

```
procedure RUN-ENVIRONMENT(state, UPDATE-FN, agents, termination)

inputs: state, the initial state of the environment

UPDATE-FN, function to modify the environment

agents, a set of agents

termination, a predicate to test when we are done

repeat

for each agent in agents do

PERCEPT[agent] ← GET-PERCEPT(agent, state)

end

for each agent in agents do

ACTION[agent] ← PROGRAM[agent](PERCEPT[agent])

end

state ← UPDATE-FN(actions, agents, state)

until termination(state)
```

- ➤ Agents are typically designed to work correctly in a class of environments (that has to be covereby a simulator somehow).
- ➤ Agent programs should not have other access than percepts to the state of the program simulating their environment!

T-79.230 / Spring 2005

Intelligent Agents

➤ The performance of agents can be measured by inserting special measurement code to simulator programs.

- ➤ An agent program maps a percept (sequence) to an action.
- ➤ Agent = architecture + agent program.
- ➤ A rational agent tries to maximize its performance measure.
- ➤ Task environments can be described by PEAS descriptions.
- ➤ Various agent types: reflex agents with(out) internal state, goal-based agents, utility-based agents.
- ➤ Important aspects of agent program design: efficiency, compactness, flexibility.

QUESTIONS

- ➤ Analyze soccer playing agents by writing down
 - 1. a PEAS description and
 - 2. the main properties of the environment.
- ➤ Consider the following designs for soccer playing agents:
 - 1. Simple reflex agent
 - 2. Model-based reflex agent
 - 3. Agent with explicit goals
 - 4. Utility-based agent
 - 5. Learning agent

What kind of functionality can be implemented in terms of these?
